*Demos*  
*~100 Gbps*  
*Products:*  
*~33 Gbps*  
*40 GB per disk*

# Superparamagnetic Effects

- In magnetic recording
  - $\text{SNR} \propto \sqrt{n}$
  - Where  $n$  = number of grains / trackwidth
- To maintain SNR as the bit size is reduced, the grain size,  $d_0$ , must be reduced.
- If  $d_0$  becomes too small, thermal energy ( $K_B T$ ) may destabilize the magnetization and cause the recordings to decay.

# 45 Gbit/in<sup>2</sup> Demo Media (Seagate)

---

- 8.5 nm grains
- $\sigma_{\text{area}} \cong 0.5$

# Thermal Relaxation

- Relaxation time =  $\tau = 10^{-9} \exp (K_U V / K_B T)$ 
  - $\tau = 72$  sec for  $K_U V / K_B T = 25$
  - $\tau = 7.5$  years for  $K_U V / K_B T = 40$
  - $\tau = 3.6 \times 10^9$  years for  $K_U V / K_B T = 60$
- Demagnetizing fields in transitions shorten the relaxation time.
- Charap predicted that, with linear scaling, magnetic recording would reach the superparamagnetic limit at approximately 36 Gbit/in<sup>2</sup>.

# Seagate Demo of 101 Gb/in<sup>2</sup>

---

- 149 ktpi; 680 kbpi; 101 Gb/in<sup>2</sup>
- BAR = 4.6
- RW ~ 3.75 uin; WW ~ 4.9 uin
- AFC media
- Napa channel @ 256 Mb/s
- On-Track BER =  $5 \times 10^{-5}$
- OTC=10%TP; 5% squeeze; BER of  $1 \times 10^{-4}$

# The Importance of Being Square\*

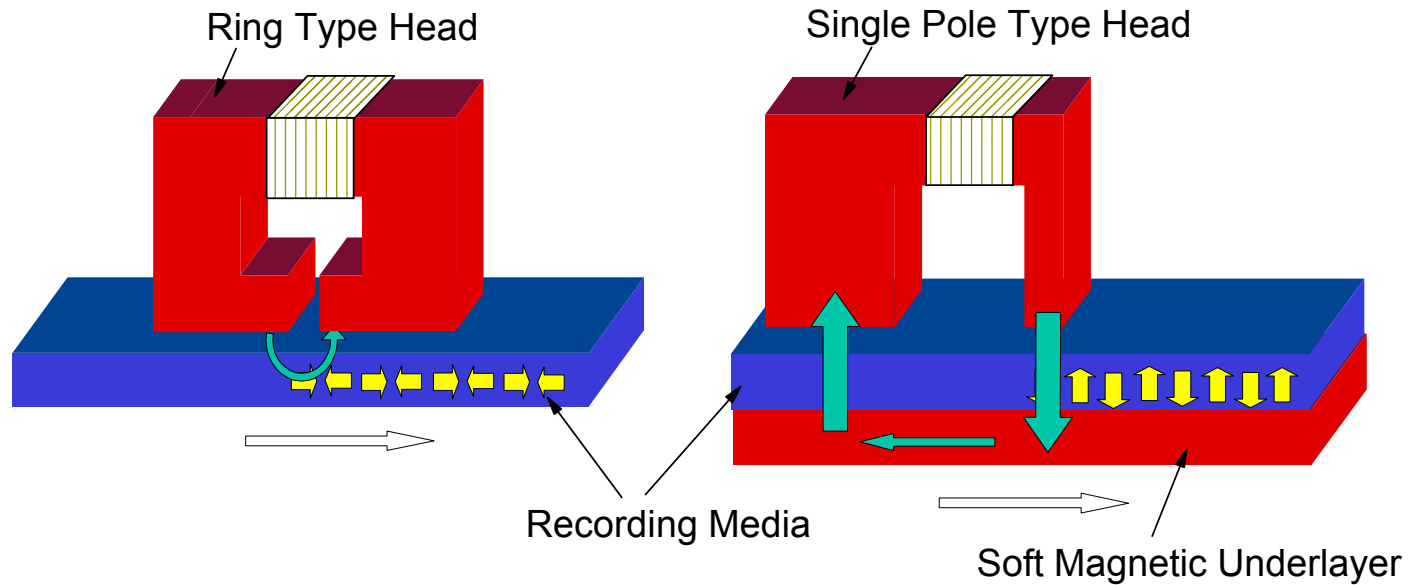

Under conditions of **constant decay rate** (grain volume and demag field constant) and **constant transition noise jitter**:

$$\text{Gain} = \frac{\text{Square Bit Density}}{\text{Rectangular Bit Density}} = \frac{1/S^2}{1/W} = 2^{2/3} \cdot W^{5/9}$$

If  $W = 20$ ,  $\text{Gain} = 8.4$

This is undoubtedly more areal density gain than can be achieved, but does indicate that more square bits are desirable.

# Longitudinal and Perpendicular Recording

Longitudinal Recording

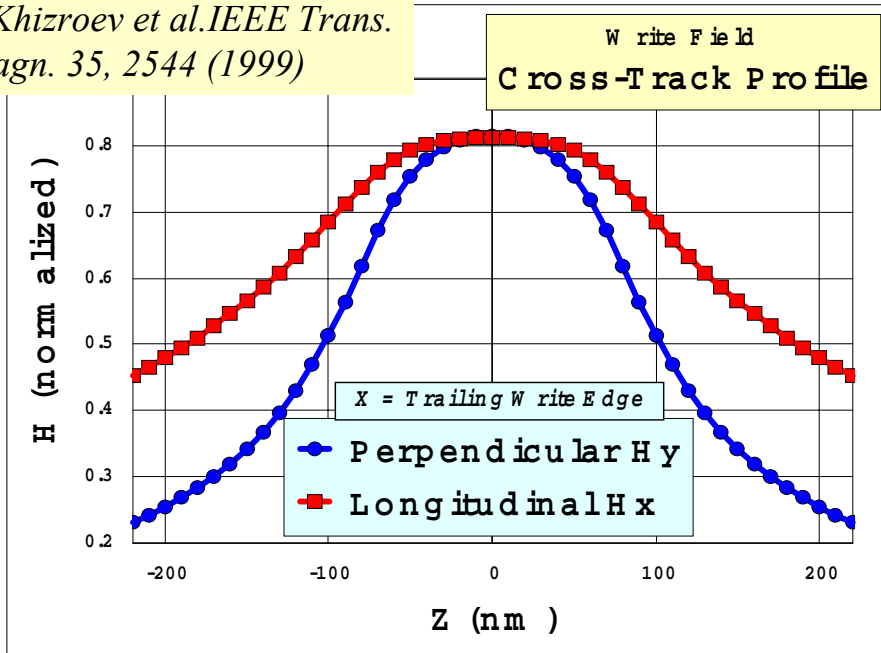

Perpendicular Recording

- *Smaller side fringing fields*
- *Potential increase in the magnitude of the write fields*
- *Potential increase in media thickness*
- *→ Higher BPI and Areal Density with Thermal Stability*

# Narrow Track Recording

S. Khizroev et al. IEEE Trans. Magn. 35, 2544 (1999)

Track width

100 nm

250 nm

500 nm

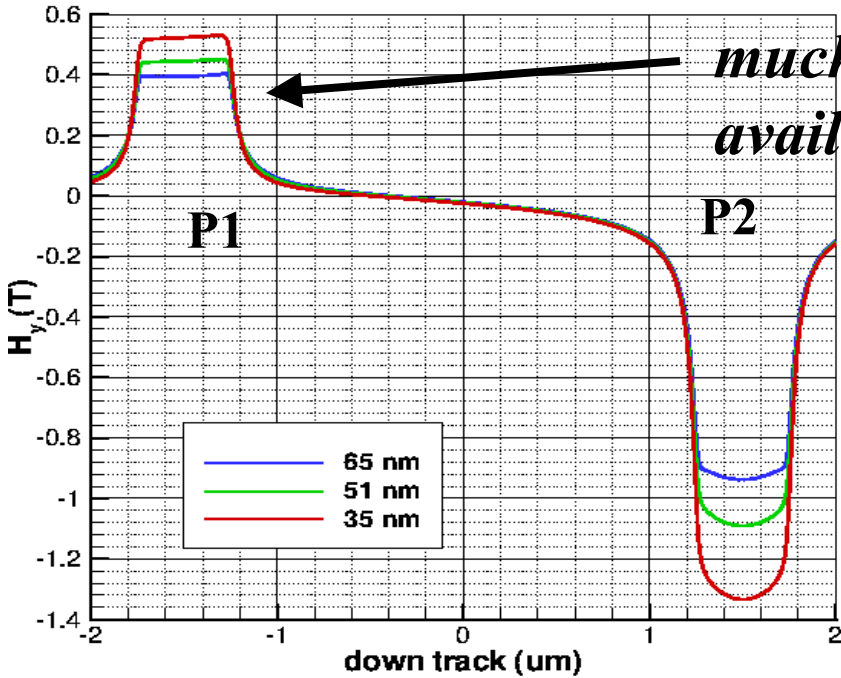

Trailing edge

# Field Amplitude / Sensitivity to Spacings

Down Track Vertical Write Field vs. HSS

**Head to Soft Underlayer Spacing is critical**

HSS=65 nm H up to 9000 Oe  
 HSS=51 nm H up to 11000 Oe  
 HSS=35 nm H up to 13500 Oe

$$\text{ACSN} = 17.4\text{dB} + 13.34\text{dB}(\exp(-\text{IL}/4.32))$$

Reducing IL thickness from 26.5 to 5 nm improves **+4 dB** in ACSN

NAPMRC

# Perpendicular System at 1 Terabit/sq.in. (650 Gbps User Density)

**Areal Density:** 1 Terabit/sq.in. ( $1.6 \text{ Gbit/mm}^2$ ) (including Channel overhead; excluding ECC overhead)  
 $= 1.85 \text{ Mbits/inch}$  ( $73 \text{ Kbits/mm}$ )  $\times$   $540 \text{ Ktracks/inch}$  ( $21 \text{ Ktracks/mm}$ )  
 (Bit aspect ratio is 3.5:1; required racking accuracy  $= 0.3 \mu\text{m}$  (7 nm)  $3\sigma$ -2pass)

**Medium:** Perpendicular with soft underlayer:  $H_c = 12,000 \text{ Oe}$  ( $1 \text{ MA/m}$ );  $M_r = 6360 \text{ Gauss}$  ( $510 \text{ EMU/cc}$ )  
 Thickness =  $0.36 \text{ microinches}$  (9 nm);  $M_r t = 0.45 \text{ mEMU/cm}^2$   
 Grain-diameter:  $8 \text{ nm} \pm 1 \text{ nm}$  (1-sigma) - random position and size distribution

**Read Head:** Read-width:  $1.2 \text{ microinches}$  (30 nm), Sensitivity:  $1 \text{ mV}$  peak-peak; Resistance: 50 ohms

**Write Head:** Write-width:  $= 1.5 \text{ microinches}$  (37nm); Saturation:  $B_s = 20,000 \text{ Gauss}$  (2 T)

**Head/Disk Interface:** Magnetic Spacing:  $0.26 \text{ microinch}$  (6.5nm) to top of medium;  $1600 \text{ inches/s}$  (40 m/s) max.

**Read Channel:** Detector SNR: 9.5 dB (rms/rms) allowing  $\sim 3\text{dB}$  system margin; Max. data-rate =  $3 \text{ Gbit/s}$ ;  
 Channel: 5/6-rate simple parity; ECC: RS(556, 410), GF $2^{10}$ , overhead = 35%

# Perpendicular Recording Density Potential

- 1 Tbps perpendicular recording proposal is challenging!
  - User density is really 650 Gbps
  - Grain size dispersion is much less than we know how to achieve with polycrystalline media.
    - Self-Ordered Magnetic Arrays might be a solution.
  - Media anisotropy/coercivity is at the limit of what can be written with conventional head materials/structures.

# Heat-Assisted Magnetic Recording (HAMR)

## Hybrid Recording Using Light

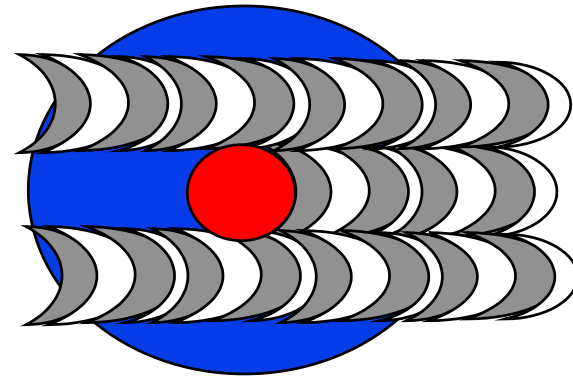

# Different Approaches to HAMR

Far Field Light Delivery System:

Near Field Light Delivery System with Global Magnetic Field:

Near field light delivery system defines track-width; magnetic head defines bit length:

Near field light delivery system and magnetic head co-located to define bit and track:

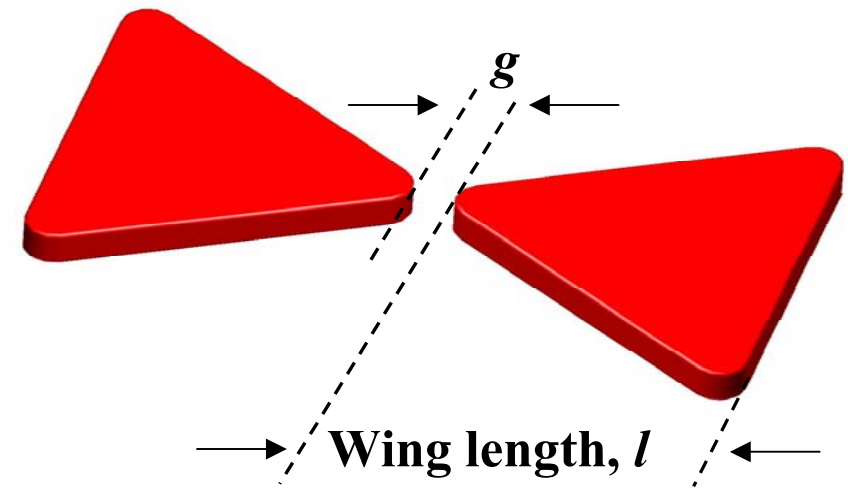

# Bowtie antenna

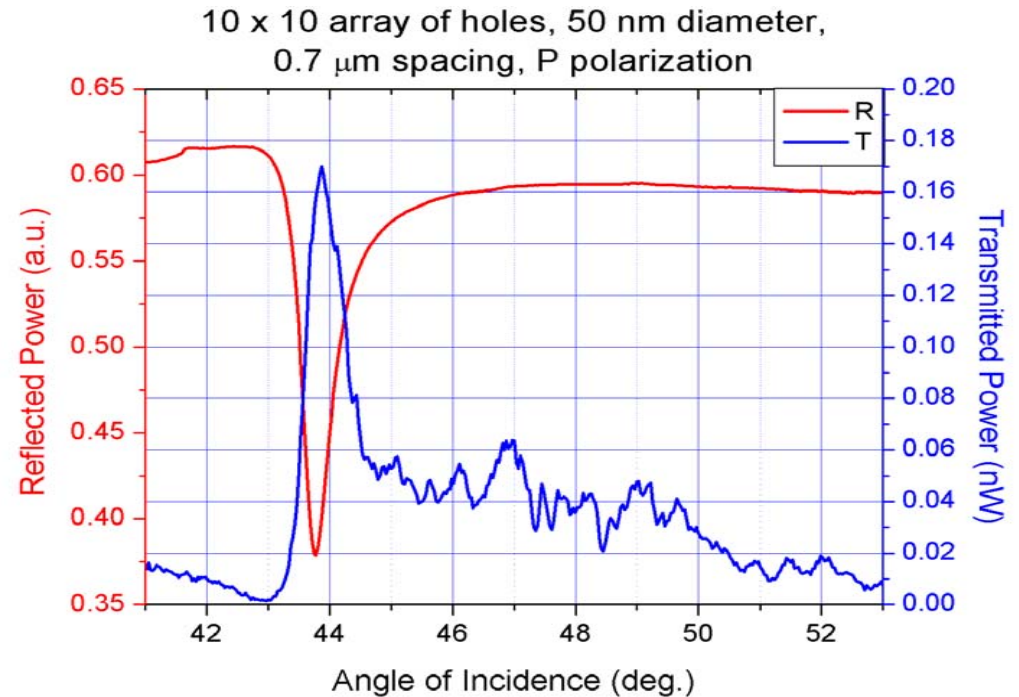

U.S. Patent 5,696,372

R.D. Grober et.al., Dec. 9, 1997

**“High Efficiency Near-Field  
Electromagnetic Probe Having a Bowtie  
Antenna Structure”**

# Light Transmitted Through Array of 50 nm Holes

Incident power density:  $0.14 \text{ mW}/\text{mm}^2$

Ave. transmitted power density/hole:

$0.87 \text{ mW}/\text{mm}^2$  at resonance

W. Challener

# Heat Assisted Magnetic Recording

---

- What areal density might be achieved with HAMR?
  - HAMR could make it possible to use the smallest possible thermally stable grain, irrespective of the anisotropy/coercivity.
    - In FePt, this is about 3 nm.
  - If perpendicular recording can achieve 500 Gbpsi with 8 nm grains, then HAMR should be able to achieve about 10X higher density.

# Patterned Media Recording

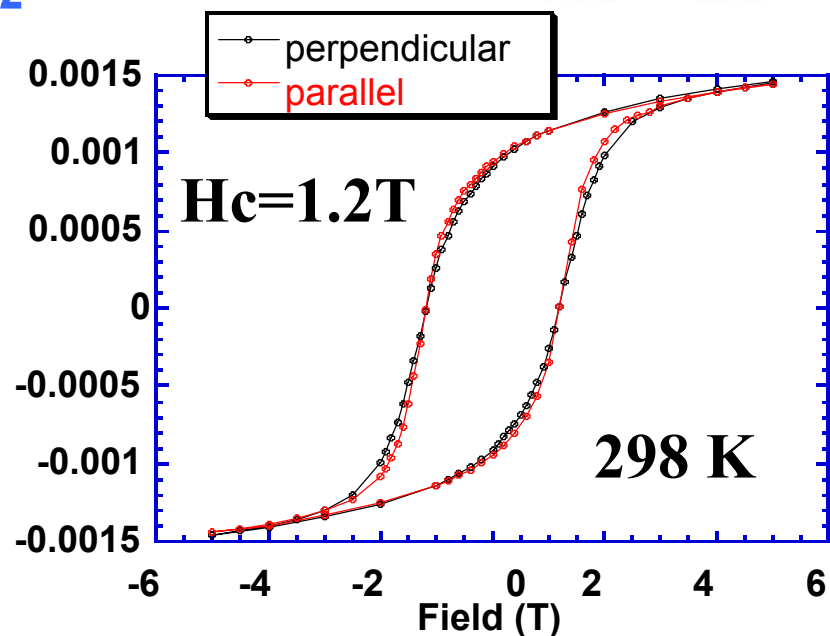

---

- Major obstacle is finding low cost means of making media.
  - At 1 Tbps, assuming a square bit cell and equal lines and spaces, 12.5 nm lithography would be required.
  - Semiconductor Industry Association roadmap gives no hope of achieving such linewidths within the next decade.
  - E-beam and X-ray lithography have been around for over 30 years, but during that time, there has been little progress on the minimum producible feature size.
- Numerous systems issues also exist.

# Self-Ordered Magnetic Arrays (SOMA) of FePt

Modeling:  $D = 4.8 \text{ nm}$ ,  $K_u = 4.9 \times 10^7 \text{ erg / cm}^3$ ,  $\text{exch} = 0.2$

Shukla, Liu, Wu, Klemmer, Chantrell, Lu, Ahner, Weller (to be published)

# SOMA Media - Obstacles to Overcome

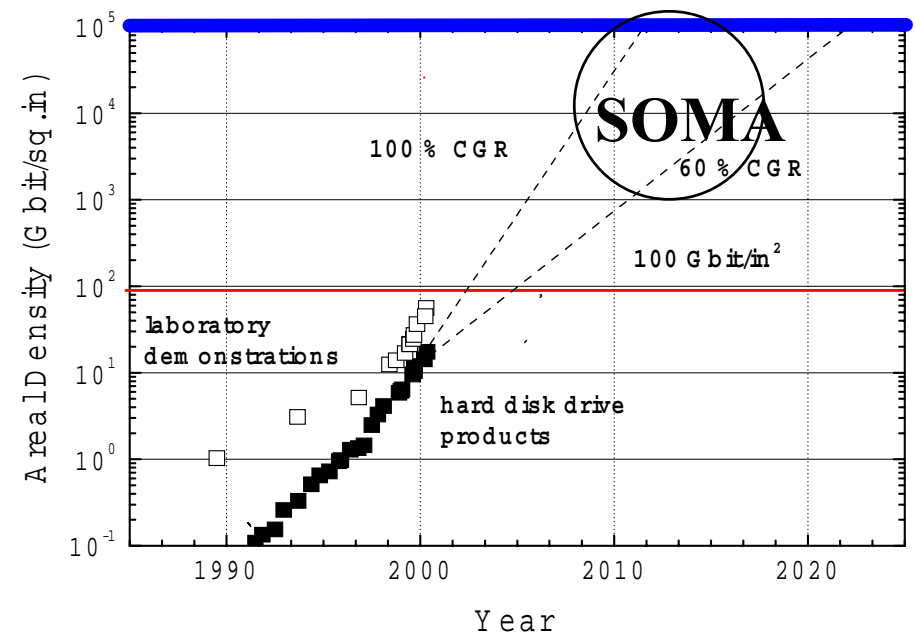

---

- SOMA do not form in concentric tracks.
- To achieve the highest areal density, we will still need improved means of writing.

# HAMR with SOMA Media: The Ultimate Potential?

- HAMR could make it possible to write on FePt.
- With single particle/bit recording, and 3nm stable particles, the potential is over 50 Tbps!

## Naturally Patterned SOMA Structure (nm scale)

# Conclusions

---

- Longitudinal recording is expected to approach limits somewhere beyond 100 Gbps.
- Perpendicular recording appears promising for extending the areal density progression -- perhaps to 1 Tbps.
- Heat assisted magnetic recording could extend the areal density to 5 Tbps.
- SOMA media, in combination with HAMR offer an ultimate areal density of 50 Tbps.
